

## Making Sense of Medicine: Biophotons: The light of life

**Making Sense of Medicine Bob Keller Oct 17, 2019**

**Newburyportnews.com**

**Did you ever have that feeling of a close connection with a person you just met? Can you sometimes sense the mood of another person without actually seeing them?**

It must be about qi or prana or auras or other weirdness. You know, all that far-out stuff you hear about those invisible meridians, healing energy pathways, and dah, dah, dah ... bunch of nonsense!

The thing is that for thousands of years, countless millions of people have experienced verifiable communications and energies and healings that can't be explained in rational terms. Or can they?

### **Light from an onion**

**Making Sense of Medicine Bob Keller Oct 17, 2019 Newburyportnews.com**

In 1923, a Russian cell biologist, **Alexander Gurwitsch**, discovered extremely low-level ultraviolet light emitted from onions. He called this mitogenic radiation, and his work was used in diagnosing cancer. In 1941, he was awarded the prestigious Stalin Prize for his work.

However, 500 failures to duplicate his research results led to his work being discredited. Later in the 20th century, however, it was taken up by his daughter, Anna, and by others. In the 1970s, German cell biologist **Fritz Albert Popp** coined the currently used term "biophoton" for this light.

### **What is a biophoton?**

When thinking about light, we usually think about light waves. Light waves are a kind of electromagnetic radiation that we can see and that has color, based on how fast the wave is vibrating, its frequency. Lower frequencies are toward the red color, and higher frequencies toward violet. There are also those frequencies that are slower than red, infrared, and faster than violet, ultraviolet, that we can't see with the naked eye.

The interesting thing about light is that in addition to behaving like a wave of energy, it can also behave like a physical particle, a kind of chunk of light, a quantum. It's this basic unit of light that we call a photon.

Biophotons are photons, bits of light, that are generated spontaneously by most living cells. Research suggests that biophotons are created in the DNA that resides in the mitochondria in your cells. They are created in the 98% of each DNA molecule that is not used for genetic coding of behavior. The genome project referred to this as junk-DNA because they had no idea about its use.

All of your cells, except red blood cells, emit biophotons, but only a few dozen of them per square inch. Because of this paucity, the intensity is very low, by which I mean it's like looking at a candle that's about 6 miles away from you.

I should say here that research into understanding biophoton creation and function is still in early stages. So, while a lot has been discovered, and some interesting probabilities lie ahead, one might preface much of what I say with the word **“probably.”**

### **Why care about biophotons?**

Everything that goes on in your cells is relevant to your health and well-being; this includes biophotons. We'd like to know how their existence and behavior can be used diagnostically, as Gurwitsch began to do with cancer in the early 20th century. We'd like to know how biophotons are used in communication between cells. We'd like to know how biophotons affect people and objects around us.

### **Communication**

Interesting is research into biophotons' role in communication inside and outside your body. At base, what is now known is that your cells' DNA not only emits light, but it absorbs it, as well. The experimental implication is that biophotons are a means of communication among your cells, communication that occurs at the speed of light — 186,000 miles per second. It is now generally accepted that the coordination among cells in your body, coordination that happens within milliseconds and even shorter times, is orchestrated by biophotons.

For such communication to take place, there needs to be not only a sender and a receiver, but also a “language” that is understood by both sender and receiver. Interestingly, as early as 1994, researchers at Harvard Medical School discovered patterns of syntax and grammar in your junk-DNA that are common to all the world's natural languages. Thus, it seems that your biophotons and mine may speak a common language.

### **Interpersonal communication**

Can you be unconsciously affected by biophotons sent from someone else? It is generally accepted that communication does go on between humans and other organisms at the unconscious level. While much is left to be proven, research is suggesting that such communication is related to biophotons.

In other words, before you say a word to another person, your bodies may already be in unconscious communication. And so, yes, you may sense affinity or the opposite. And, yes, you may feel their anger or joy without any outward indication.

### **Implications for health care**

In your body, at the cell level, free radicals are the terrorists. They are a natural byproduct of your body's turning food into the energy you need for everything you do as part of living. Free radicals have one thing in common, which is that they are missing one electron, and so they feel incomplete. Thus, they are constantly seeking to steal an electron from other stable compounds like your DNA. Such a theft can change unpredictably the nature and function of your genes.

If there is a preponderance of free radicals in your system, there is oxidative stress. One possible use of biophotons could be in diagnosing oxidative stress. This is possible because we observe that in a state of oxidative stress, many more biophotons are created than when such stress is low.

It's not just free radicals that increase what's called ultraweak photon emission. Any stress to the skin, such as the ultraviolet radiation in sunlight or cigarette smoke, increases UPE. Conversely, applying vitamin C or other antioxidants reduces UPE. One implication of this is the possibility of assessing not only oxidative stress but aging conditions, as well.

The National Institutes of Health has produced considerable literature on the medical implications of biophotons, including biophoton participation in our experience of consciousness, self-awareness.

With regard to qi and prana and auras and the like, biophotons are definitely involved. However, the reality is more complex and requires an exploration of torsion fields, which is beyond the scope of this column.

## Quantum medicine

There is also an assortment of "quantum" medical practices that claim to use biophotons to heal everything you might have. To the extent that these are credentialed practitioners, like chiropractors, for example, they probably do some good. My reading of reviews of quantum medicine, however, suggests that it is largely quackery. A famous, and usually credible, advocate of alternative methods, Deepak Chopra, coined the term quantum healing. Scientists have characterized his descriptions as "incoherent babbling strewn with scientific terms."

## What to do about biophotons

I'm writing about biophotons simply to introduce an area you've probably never encountered, an area that may have profound implications for a more balanced and personal health care system in years to come. We need a system that knows not only how to drug and dissect your physical and psychological problems, but one that knows also how to integrate the energetic underpinnings of life.

Bob Keller maintains a holistic practice in Newburyport. He offers medical massage therapy for pain relief, as well as psychological counseling, dream work and spiritual direction. Many patients call him Dr. Bob and accuse him of doing miracles, but he is not a medical doctor nor a divinity. His expertise is medical massage therapy, understanding this miracle we call the human being. He can be reached at 978-465-5111 or [rk2name@gmail.com](mailto:rk2name@gmail.com).
